TRANSILLUMINATION

The principle of venous transillumination is using the difference in refraction and absorption of light at the tissue level to highlight a large portion of the intradermal venous network located in the first three sublevels of the epidermis. Light penetration (specific wavelength) differs depending on skin type (Fitzpatrick classification). Transillumination allows the visualization of varicose veins that is not possible to achieve with the human eye, and provides therapeutic safety because the darker the skin, the greater the risk of pigmentation.

VISUALIZE THE VEINS AT DIFFERENT DEPTHS

THE ROLE OF TRANSILLUMINATION IN SCLEROTHERAPY

- Visualize and treat varicose veins
- Helps marking
- Visualize the source of reflux
- Assures you are in the lumen
- Visualize the passage of the product and the vein spasm

TRANSILLUMINATION

A COMPLETE SOLUTION

An ergonomic design means it is **easy to use** the system with one hand and to handle a syringe with the other hand to allow sclerotherapy guided by transillumination. These improvements bring a **new concept in phlebology**: preventive or early treatment of varicose veins and telangiectasias. The progress made in the use of transillumination with Venolux® marks a very beneficial contribution in the fields of diagnosis and therapy in phlebology.
